# *Monitoring and Experiments*

Carl Beierkuhnlein

*Field Survey in Eastern-Morocco (Debdou)*

# *Ecological Monitoring*

---

Ecological Monitoring can be applied

- for the detection of spatial patterns and
- for the detection of spatial trends

The design of the sampling has to relate to either spatial or temporal foci.

# *Sampling*

---

As it is not possible to cover a target unit (e.g. ecosystem) *completely*, the selection of a sample is required. This has to follow certain prerequisites.

Sampling has to be:

- Representative for the data set
- Non-redundant and not autocorrelated
- Efficient in time, space and money
- Independent from observer bias
- Repeatable within relevant time scales
- Adequate to the problem

# *Sample Size*

---

A sample is number of observations (measurements, records, plots) that is related to a certain phenomenon under investigation or survey.

The sampling is aiming to represent the whole unit (e.g. landscape, ecosystem, catchment).

Sampling can be based on experience and knowledge but also on probability theory and statistics, depending on the individual case.

# *Grain and Extent*

---

In Ecology, scale is mostly addressed in two hierarchical ways (following Allen & Hoekstra 1991).

„grain“ (resolution, support, sub-unit)

- a) specific plot (observation) area
- b) point in time of a record (observation)

„extent“ (whole unit, entirety, range)

- a) complete investigation area
- b) duration of a time series

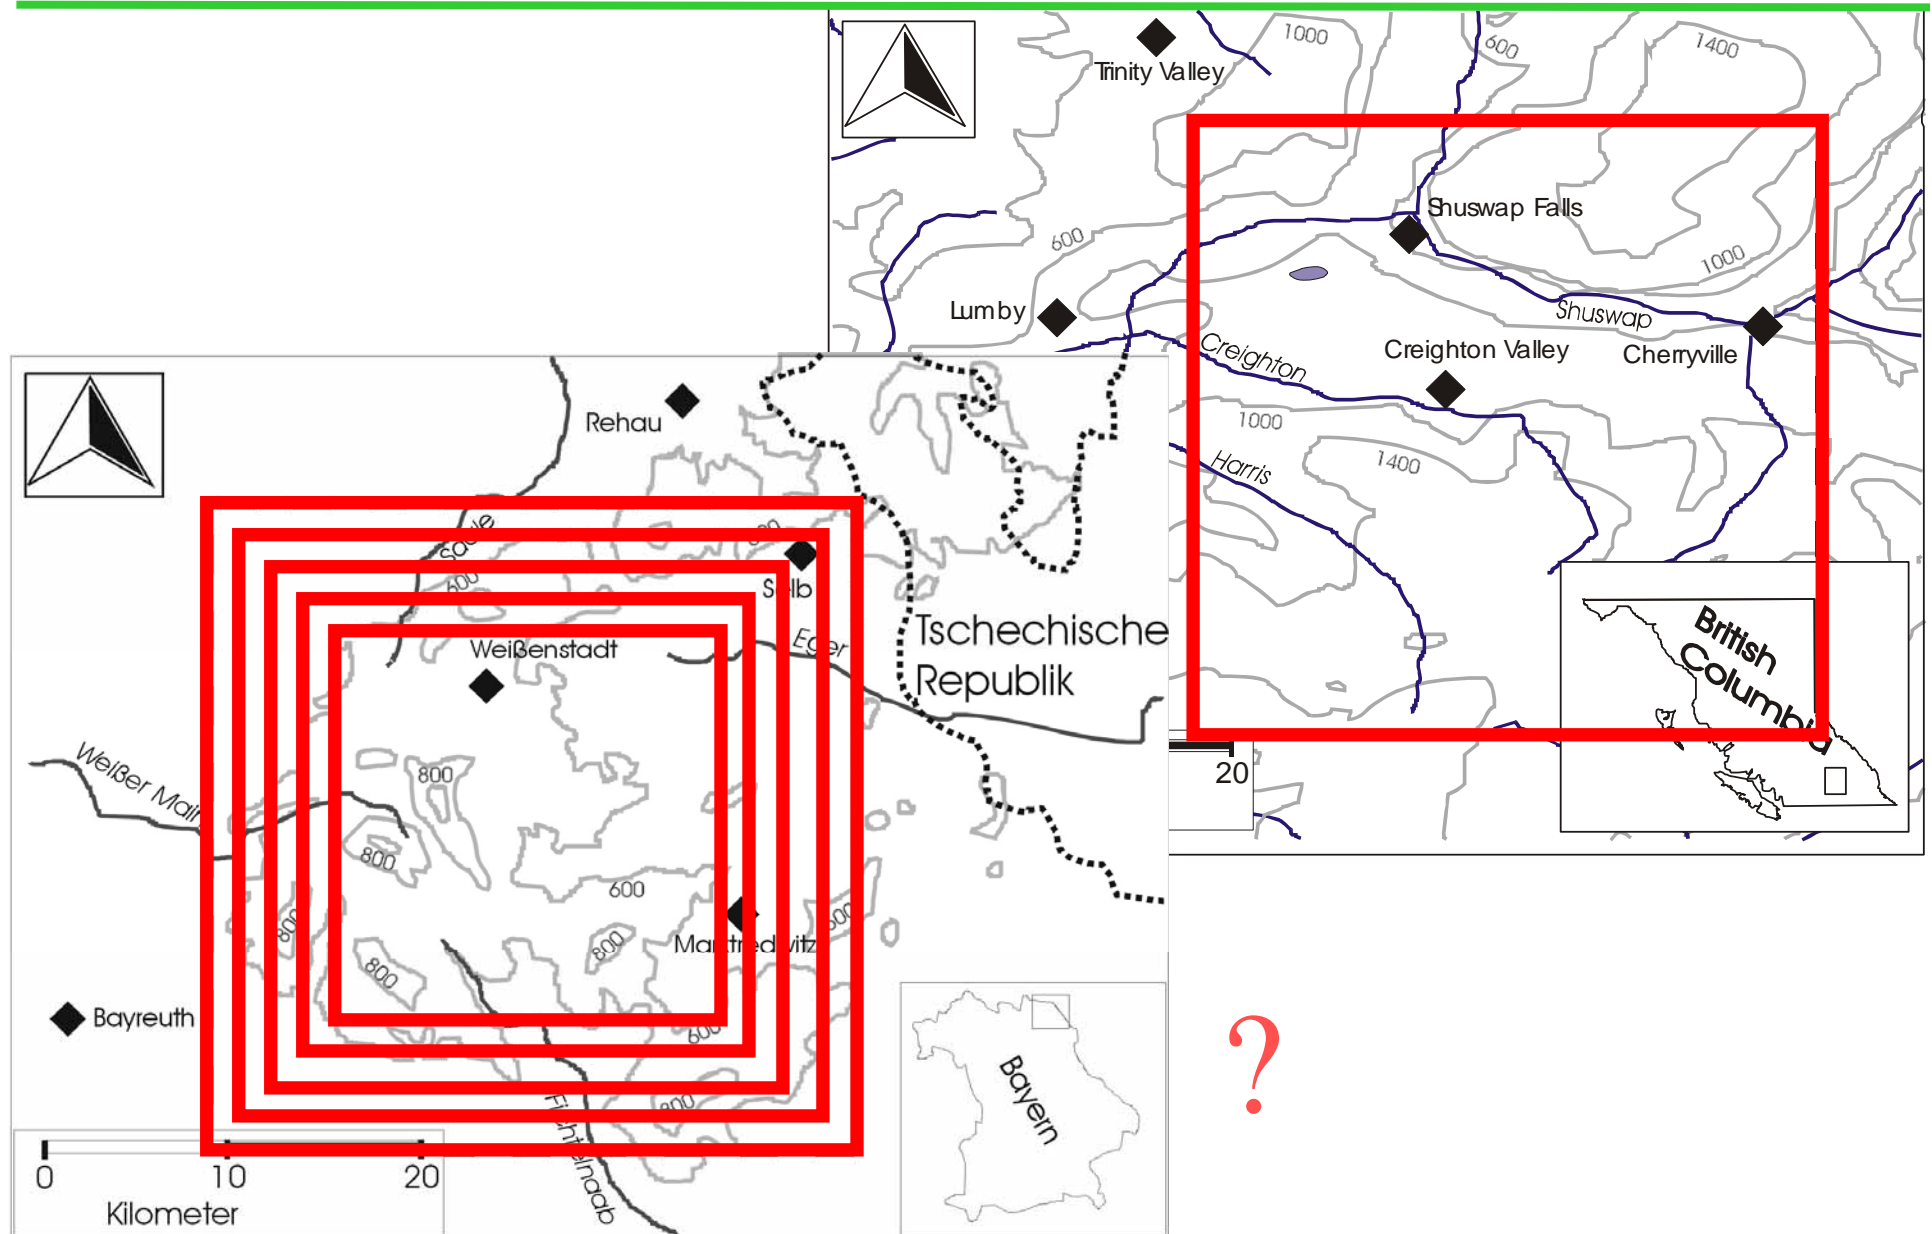

# *Grain and Extent*

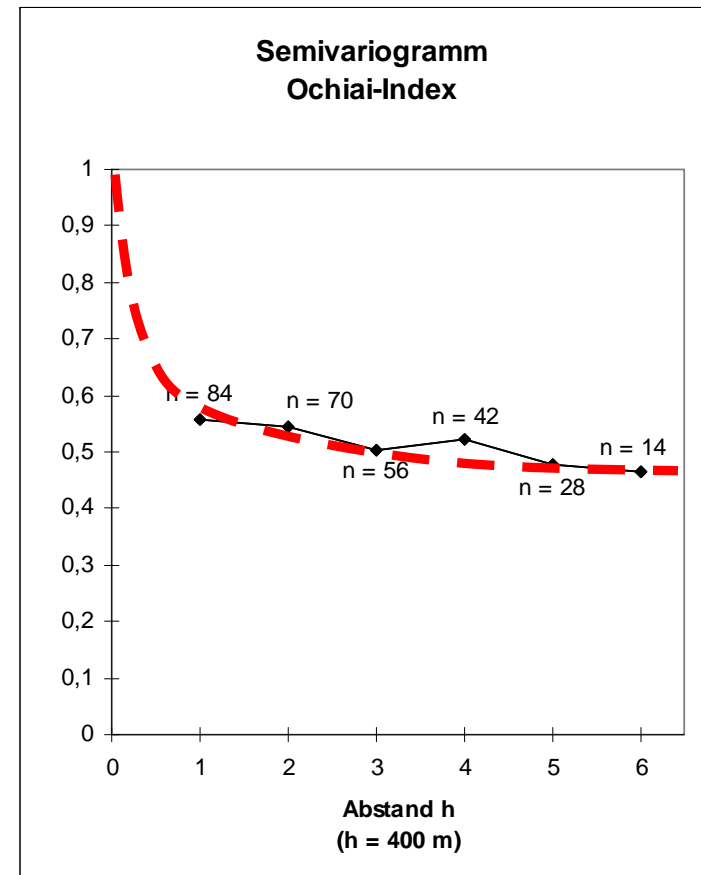

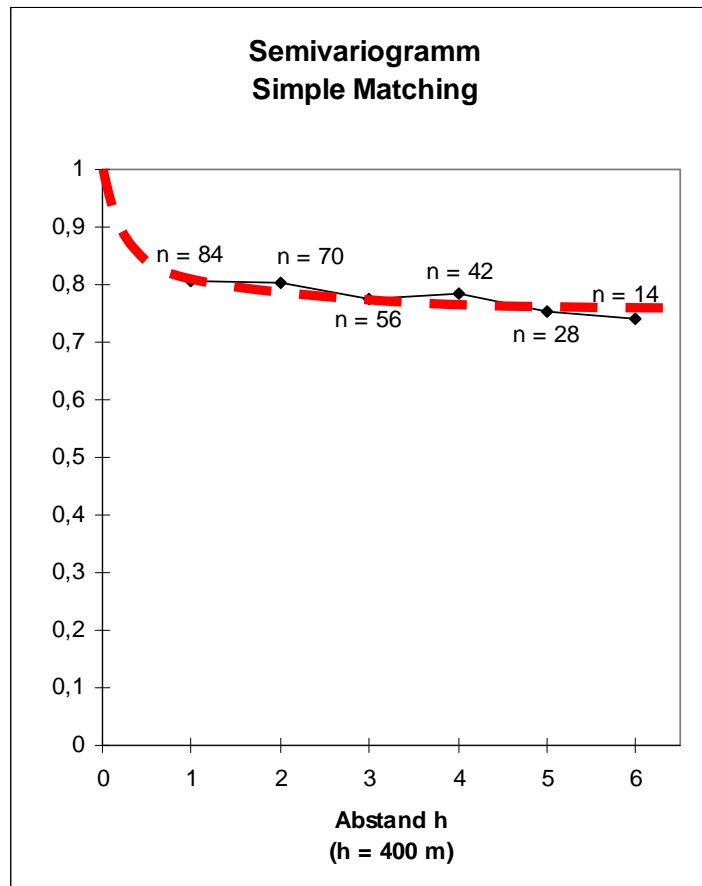

# *Grain and Extent*

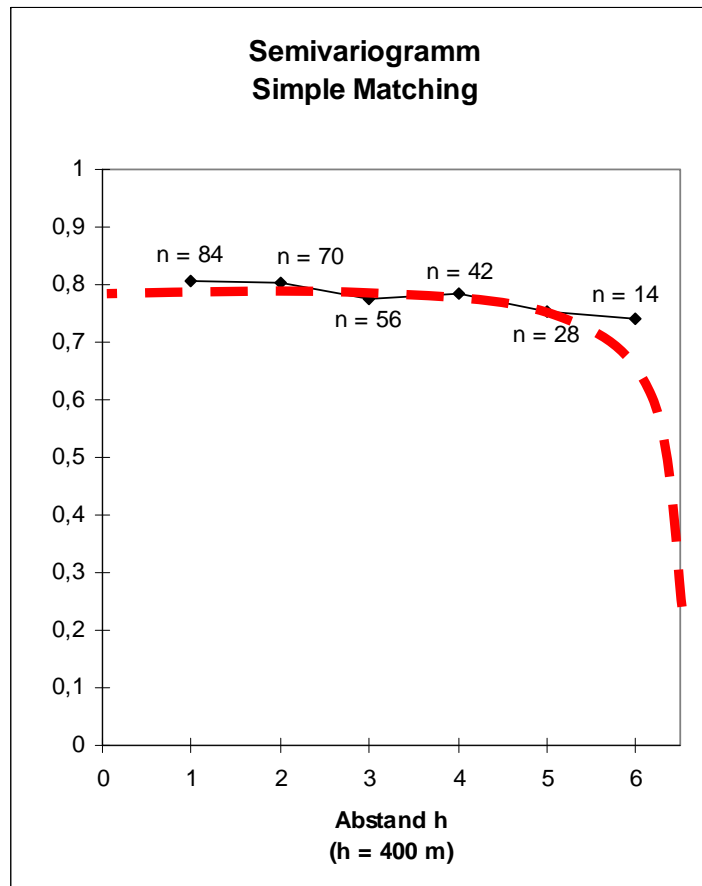

# Grain and Extent

# Grain and Extent

# *Sample Quality*

---

Each single observation may be a composite of different qualities. These can be defined as „variables“ (e.g. species, compounds, temperature).

Variables can be differentiated into dependent (e.g. ANPP) and independent ones (e.g. species diversity). ANPP may be found to depend on species diversity.

A „parameter“ relates functions and variables.

If species composition (or fertilisation, or temperature, or moisture) is changing for instance, ANPP may increase even if species diversity remains the same.

# *Choice of Objects*

---

Investigation areas, plots, transects, time series etc. are performing a certain variability.

This may be seen as the background or stochastic „noise“, which has to be identified but is not related to the target question.

However, variability may follow certain rules and causes that refer to the problem or research question (e.g. „changes“).

# *Ecological Monitoring*

---

For both sampling approaches - temporal and spatial - three major categories of options exist:

- Random (stochastic)
- Systematic (regular)
- Preferential (pre-defined, expert knowledge)

The choice of an approach depends on research question and on temporal as well as spatial scales.

# *Spatial Sampling*

# *Spatial Sampling*

random

# *Spatial Sampling*

# *Spatial Sampling*

## Systematic Mistake

- Underlying gradients may not be recorded
- Causes may be regularities in space or regular processes in time (seasons)

# *Spatial Sampling*

# *Spatial Sampling*

# *Spatial Sampling*

# *Spatial Sampling*

# *Spatial Sampling*

# *Spatial Sampling*

---

# *Sampling*

---

- systematic
  - random
  - preferential
- ➔ objective  
but perhaps ignorant
- ➔ biased  
but perhaps based on  
expert experience and  
knowledge

# *Heterogeneity*

---

Heterogeneity refers to a specific dataset (e.g. area, time). Considering this dataset as one unit, we may analyse the variability (range of data) within this unit.

Scales differ. We may relate heterogeneity to

a') one specific plot

b') one area of investigation

a'') one point in time

b'') one time series

# *Spatial Heterogeneity*

---

## Heterogeneity

„Range of dissimilarity between units within a dataset “

„Texture of objects“

## *Dissimilarity*

„Variability (Difference) between two units (beta-Diversity)“

„Contrast between objects“

## *Pattern*

„Non-random spatial or temporal organisation within a heterogeneous set of data “

„Arrangement of objects“

# *Distance Decay*

---

*„Everything is related to everything else,  
but nearby things are more related than  
distant things“*

Waldo R. Tobler, 1970

# *Distance Decay*

---

In functional geography (e.g. economic geography) **distance decay** is used as a term that may be quantified to indicate accessibility or the intensity of interaction between units or locations.

# *Distance Decay*

---

Thünen'sche Kreise  
Thuenen's Circles

**Johann Heinrich  
von Thünen  
(1783 - 1850)**

Developed the theory on spatial differentiation due to increasing distance (originally for agriculture and gardening). His concepts were adapted during the 20th century in spatial planning (eg. „Konzept der zentralen Orte“) and in economic geography.

# *Distance Decay*

Wackernagel, H. (1995): Multivariate Geostatistics. An Introduction with Applications. Berlin, Springer.

# *Ecological Scales*

# *Temporal Scales*

# *Spatial Scales*

# *Distribution*

Clumped aggregates of units (species) may cause high variance in the data set.

Nentwig, W., Bacher, S., Beierkuhnlein, C., Brandl, R., Grabherr, G.  
(2003): Ökologie. Spektrum/Elsevier, Heidelberg.

# *Distribution*

---

preferential

systematic

systematic

random

# *Distribution*

systematic

random

in %  
of plots

Small units show high variance in the data set

# *Distribution*

---

- simple approach
- traditional

Good for assessments of  
**alpha-diversity** patterns  
and **gamma-diversity**

- equidistant neighbours
- no cross-similarities

Good for assessments of  
**alpha-diversity** and  
**beta-diversity** patterns  
and **gamma-diversity**

# *Distribution*

# *Cyclic Sampling*

Case study of a „pre-investigation“

Target: Identifying minimum distances

Hypothesis: Distance decay of similarity

Amount: 10 records

Groups: 5 pairs in 30, 60, 90 and 120 m distance

Result: 90 m most appropriate

# *Cyclic Sampling*

---
